### **Abstract:**

The policies are made looking at the macro estimates. But today more and more policy makers are demanding estimates at the micro level for its use in the policy decisions. The local self government such as district panchayats, tehsil panchayats and gram panchayats are taking on a greater role in the long term planning and socio-economic development of their areas. However the biggest constraint is often that data sources in the country do not readily support the ability to monitor welfare program at the disaggregated level.

Recently developed techniques such as Small Area Estimation can help fill this data gap. This is a methodology to identify areas with high levels of poverty at the lower levels of disaggregation. The analysis in this paper uses data collected by Census and National Sample survey data. We have also constructed uniform location codes between census and local self government boundaries. The study covers 30 district panchayat, 314 tehsil panchayats and 6052 gram panchayat of Orissa. And the study is limited to the rural Orissa. It also has various interesting policy as well as regulatory implications.

**Keywords:** small area estimation, poverty, local self government

## 1. INTRODUCTION

India has one of the longest histories of poverty estimation in the world. These surveys were pioneered by P. C. Mahalanobis in the 1940s and 1950s. P.C Mahalanobis was the first one in the world who had applied the principle of random sampling to the household surveys. India's official poverty estimates are based on the consumer expenditure surveys conducted by the National Sample Survey Organization (NSSO). These surveys are conducted in every five years. These are called 'thick' rounds. The first thick round survey on consumption expenditure held in the year 1973-74. Prior to 1973-74 also there were several other attempts were made to estimate the poverty.<sup>1</sup> And over the years, the design of the Indian surveys has evolved and they are continuously under discussion. The Planning Commission uses these large surveys to estimate poverty for each state. And these estimates become the basis for various transfers from the central government to the states.

It is also important to highlight here that in India two separate agencies are responsible of poverty measurement and identification of the poor. The Planning Commission is responsible for poverty measurement and the Ministry of Rural Development in association with the State Governments identifies the poor households for selection of beneficiaries under the poverty alleviation programmes. Given that the money for these targeted programmes often comes from the central government, there will be a tendency to overestimate the numbers of poor households by state government and local self government.<sup>2</sup> And the government tries to cap this by using the state level poverty estimates.

As mentioned above, most of our welfare programmes are targeted programmes for those below the poverty line (BPL), identification of the poor becomes very important. There is a general move towards a decentralized form of identification where local officials along with

---

<sup>1</sup> Dandekar and Rath (1971); Bardhan and Srinivasan (1974); Rudra (1974). The list is not exhaustive.

<sup>2</sup> The Indian parliament passed the Local Self Government Acts through two amendments of the Constitution (73rd for Panchayats and 74th for urban bodies) in 1992. Article 243G and 243W of the Constitution provides for devolution to empower Panchayati Raj Institutions (PRIs) and Urban Local Bodies (ULBs) to function as institutions of self-government for the twin purposes of (i) making welfare plans and ii) implementing these plans subject to such conditions as the State may, by law, specify.

the gram panchayats list their poor.<sup>3</sup> They send their list to the tehsil panchayats where assessment and evaluation is done.<sup>4</sup> Then, the tehsil panchayats submit these lists to the district panchayat, where further evaluation and approvals are given to those considered as poor.<sup>5</sup> However, this process might vary state to state (refer Figure 1).

In India, the tier of governance goes from the Central to State government. Below the State government there are several local self governments. Each State has legislated to create three levels of local self governments (refer Figure 1). In the rural area, the local self government consists of district panchayats, tehsil (block) panchayats and gram panchayats. In urban areas, the local self government consists of municipal corporations in large cities, municipalities in smaller cities and towns and Nagar Panchayats in smaller towns which are in the transition phase. As per the Thirteenth Finance Commission report, there are 249918 rural local self governments and 3842 urban local self government in India. The 73rd and 74th Amendment Act, 1992 granted the constitutional status to the third-tier government in rural and urban areas. The constitutional status necessitated greater role of the local self governments in planning for economic and social development, building physical infrastructure and in decreasing poverty and regional inequalities. So it is important to know for such a decentralized planning do we have data?

There are twenty-nine and eighteen items of responsibilities listed in the eleventh and twelfth schedule of the constitution to be performed by the local self government in rural and urban respectively. These responsibilities include primary education, basic health, family planning, urban poverty alleviation, regulation of land-use, construction of buildings, local water supply and sanitation, urban poverty alleviation etc. And for the effective implementation of development programs appropriate databases are required. It will help in effective monitoring and evaluation of various social development programs including changes in health care, demographics, education, employment and incomes at the district and tehsil level.

Thus, the need for appropriate databases at lower levels of disaggregation has become imminent. India has a population of 1.13 billion. And a district in India with an average

<sup>3</sup> ‘Panchayat’ is an institution (by whatever name called) of self-government constituted under article 243B, for the rural areas; ‘Gram Sabha’ is a body consisting of persons registered in the electoral rolls relating to a village comprised within the area of Panchayat at the village level.

<sup>4</sup> ‘Tehsil Panchayat’ is between the village and district levels specified by the Governor of a State by public notification to be the intermediate level.

<sup>5</sup> ‘District panchayat’ is within a state boundary.

population of about two million cannot be considered as a “Small Area” in the statistical sense. The government used thick round surveys to estimate welfare indicators. However these surveys are representatives at the State and NSSO State region level only.<sup>6</sup>

So it's important to ask ‘How are funds to be allocated across the states and within the state? Many of these programs are centrally funded but implemented at the local self government. And most of these programs are targeting the poor population. A daunting challenge is to ensure that tools for monitoring how money is spent and what impact that has are available, so that these programs can be improved in mid course to achieve the stated objectives. However the biggest constraint is often that data sources in the country do not readily support the ability to monitor poverty at the district level or below. It is also interesting to note that in this lengthy history of poverty estimation, none of the poverty numbers were estimated below the State or State Region by the Government.

The poverty estimates in India has been based on univariate approach i.e. head count ratio. As per the NSSO surveys, rural poverty has declined from 46 percent to 23 percent between 1983 and 2009-10. And the national level poverty estimates give the impression that conditions within a country is uniform. However at the state level the significant geographic variation in the incidence of poverty may be due to differences in resource endowments, education, health services, physical connectivity and a list of other reasons. As a result we find the distribution of monthly per capita consumption expenditure (MPCE) showing the difference in the level of living among the different segments of the population. And this in turn helps in planning and decision making process to allocate the nation's resources among the sectors, regions, socioeconomic groups and access the ‘inclusiveness’ of economic growth.

The main aim of this paper is to measure poverty at the disaggregated level. In India, the responsibility of implementation of most social development programs now rests with local self government. We will estimate poverty at the local self government level. This is a very first attempt to estimate poverty at the local self government. Though there have been prior attempts to estimate poverty at the disaggregated level by Gangopadhyay et al. (2010). But it

---

<sup>6</sup> State Region is a group of contiguous districts having similar geographical features, rural population densities and crop-pattern. Generally, the regions was not found cutting across district's boundaries in any state except Gujarat.

was not at the local self government level, rather they used administrative unit the level of disaggregation. It is very important to choose the level of disaggregation where decision and implementation is done. And in India, the local self government is responsible for identification and implementation of welfare programs. However till now there has been no mapping of local self government boundaries in India. In this paper we have done the painstaking exercise to map local self government. There are 30 district panchayat, 314 tehsil panchayats and 6236 gram panchayat in Orissa.<sup>7</sup> So this paper has done a value addition in terms of creating Panchayat database as well as poverty estimation at the Panchayat level. And the focus of this study is limited to the rural area.

Historically, there were several attempts made to estimate disaggregated poverty. The literature was pivotal to improve targeting of development interventions. They have long been recognized as central to achieve greater impact in poverty reduction efforts. Papers by Kanbur (1987), Ravallion and Chao (1988), Glewwe (1991), Ravallion (1993), Baker & Grosh (1994) and Gelbach and Pritchett (2002) provides the methodology for estimating disaggregated poverty. Kabur (1987) paper provides a general framework for analyzing imperfect targeting. While Ravallion and Chao (1988) demonstrated that the targeting problem is described as the minimization of some poverty measure subject to a given transfer budget, by using as sole information the location of individuals. Glewwe (1991) suggested using the regression techniques on household survey data to predict incomes based on observable household characteristics, household assets, education and community infrastructure. And then distribute transfers on the basis of these predictions. Ravallion (1993) looked at the potential of regional targeting through budgetary grants in Indonesia. The finding suggests that the lowest level at which household survey data provide reliable estimates of poverty – improves targeting but only to a modest extent. The empirical evidence suggests that geographic targeting is particularly effective for poverty alleviation (Baker and Grosh, 1994) and is easier and less expensive to monitor and administer than other methods. On the other hand, Gelbach and Pritchett (2002) argued that the political economy considerations are likely to influence options for resource mobilization. In our paper, we use predicted expenditures from census data unlike most papers where observed consumption data have been used from the household surveys. We used Elbers, *et al* (2002) algorithm to solve the optimization problem in targeting poor in smaller units. Elbers *et al*

---

<sup>7</sup> We have been able to map 6052 out of the 6236 gram panchayat in Orissa.

(2002) extend the literature on small area estimation (Ghosh and Rao (1994); Rao (1999) by developing estimators of population parameters which are non-linear functions of the underlying variable of interest , and by deriving them from the full unit level distribution of that variable.

The poverty indicator (i.e head count ratio and inequality) reflects the geographic variability that is usually hidden in the aggregate data becomes apparent. Recently developed techniques such as Small Area Estimation can help fill this data gap. This is a methodology to identify areas with high levels of poverty at the local government level i.e gram Panchayats. It helps in designing intervention schemes and allocating subsidies, resources etc. that will be used to target the most vulnerable population effectively. This methodology is used for generating poverty or inequality map. We have used Small Area Estimation methodology for the estimation of the head count ratio at various levels of disaggregation. This technique combines existing census and survey data to estimate the poverty incidence at lower levels of disaggregation than what the sample sizes of surveys such as National Sample Survey in India permit– to identify lagging regions/areas within a state/district. This new methodology based on merging of household survey and population census data are being experimented with, for identifying specific local self government levels having the worst human development outcomes. Overlaying a poverty map with other geo-referenced information such as transport infrastructure, public service centers, and information on natural resources like soil quality can also help point to the investments necessary to lift such areas out of poverty.

The paper is organized as follows. In section 2, we present the data source and issues related to the data used for estimating poverty. Section 3 describes the poverty mapping method, particularly a Small Area Estimation (SAE) method and explains how the method was executed. Section 4 illustrates the results. Section 5 lists concluding remarks.

## 2. DATA SOURCES

The analysis in this paper uses data collected by Census and National Sample survey data. We have also constructed uniform location codes between census and local self government boundaries. The present study is only for the state of Orissa. The State of Orissa was chosen because of three reasons; First, it is the poorest states in India (46.4 percent BPL population).

Second, it is the disaster prone area like drought and floods. So there are environment related issues. Thirdly, spatially disaggregated data show huge variation. And this study covers (approximately) entire rural Orissa state.

We have used both household level and amenities datasets from the census 2001. The census household dataset is about general & socio-cultural characteristics. The census household survey collects information regarding basic demographic characteristics of the households. This includes information on religion, mother tongue, languages known, literacy and educational status, characteristics of workers and non-workers, migration characteristics and fertility particulars etc. The census amenities survey collects information regarding village or town level infrastructure.

Similarly, we have used NSS 61st Round Consumer Expenditure survey held during the year 2004-05. It was conducted on the large sample basis and it was the seventh quinquennial survey on the subject. The survey provides information on monthly per capita consumption expenditure by 32 broad groups (14 food groups and 18 non-food groups) of items of consumption. The per capita consumption estimates are provided separately for rural and urban sectors of each State and Union Territory. The poverty estimates of the year 2004-05 for the Orissa is based on the consumption expenditure survey of the NSSO, which has a sample size of around 5023 households. Though, the NSS 55<sup>th</sup> consumption expenditure survey was the closest year to census 2001 survey. But we have also not considered 1999-00 as there was a problem of comparability of this year's survey with the earlier NSS rounds (Deaton and Dreze, 2002).

A typical expenditure prediction model contains not only household information, but the location characteristics as well. One of the methodological concerns in the poverty mapping exercise is that the common pool of household variables will not suffice to capture unobserved geographic effects, such as agro-climatic conditions, quality of local government administration, etc., which might still be very important in predicting the household, or individual level welfare outcome. In an effort to proxy these unobserved factors, it is important to merge, say, village, tehsil or district level data that have been compiled separately into both the census and the household survey. The census amenities dataset comprise of a wide range of variables (for example, construction of schools, public spending

figures, infrastructure availability, population, etc.). This dataset is merged with the census household as well as the NSS households using village codes.

As mentioned earlier, the boundary of the local self government has been left undefined in India. The Ministry of Panchayati Raj has not been able to map National Panchayat Directory with the Census 2001 village codes completely. But the major initiatives taken in the Census 2001 was the allotment of Permanent Location Code Number (PLCN) to each and every village within the State became useful in merging. We merged Panchayat directory (at the village level) taken from the Ministry of Panchayati Raj with the Census 2001 dataset. For this exercise, the census 2001 location code was used as based. However, some of the names of Census records do not match with Panchayat directory (spelling problem). So manually matching was done and new codes were generated. Around 10 percent of the out of the total Orissa villages (51,000 villages) were matched manually.

### 3. POVERTY MAPPING METHOD

We have used “Small Area Estimation” methodology for the estimation of the head count ratio (HCR) at various levels of disaggregation. The small area estimation for poverty maps was developed by Elbers, et al. (2002; 2003). The approach involves the estimation of a household consumption model from survey data that is then applied to individual households in the census data to predict their consumption levels. In principle, then, if these predictions of individual household consumption levels have been correctly done then one can aggregate them to any desired level such as districts or blocks or by sectors (i.e. rural or urban), to get poverty estimates at that level. Since of course, the actual method is a bit more involved and one can look at Gangopadhyay et al. (2010; 2011) for a more complete description.

There are three distinct parts to the exercise. First, a comparison of common variables across the household survey and the population census is undertaken. The idea here is to identify variables at the household level that are defined in the same way in both the household survey and the census. It is important that this common subset of variables be defined in exactly the same way across the two data sources. The common variables in these two data i.e. the census and survey are chosen on basis of similar distributional properties. The second part of the analysis involves the econometric estimation of models of consumption using the set of household-level and community variables. Extensive exploration of alternative model

specifications is undertaken so as to identify those which can more reliably and successfully serve as the foundation for predicting welfare outcomes in the census.

Successful completion of the second-stage analysis permits one to take the parameter estimates to the final part of the exercise. This stage is associated with the imputation of the poverty indicators into the census data at the household level and the estimation of summary measures of poverty, at various levels of spatial disaggregation. Statistical precision of the poverty estimates is also gauged in this stage.

## Methodology

The estimation procedure is well spelt out in Elbers et al.(2001;2002). The methodology proposed has two stages. Firstly, a model of log per capita consumption expenditure  $\ln y_{ch}$  is estimated in the survey data:

$$\ln y_{ch} = X_{ch} \beta + Z\gamma + \mu_{ch}$$

Where  $X_{ch}$  is the vector of explanatory variables for the household  $h$  in the cluster  $c$ ,  $\beta$  is the vector of associated regression coefficients,  $Z$  is the vector of location specific variables with  $\gamma$  being the associated vector of coefficients, and  $\mu_{ch}$  is the regression disturbances due to the discrepancy between the predicted household consumption and the actual value.

This disturbance term is decomposed into two independent components:

$$\mu_{ch} = \eta_c + \varepsilon_{ch}$$

Where,

$\eta_c$  is a cluster-specific effect and  $\varepsilon_{ch}$  is a household-specific effect. This error structure allows for both a location effect – common to all households in the same area – and heteroskedasticity in the household-specific errors. All parameters regarding the regression coefficients  $(\beta, \gamma)$  and distributions of the disturbance terms are estimated by Feasible Generalized Least Square (FGLS).

In the second part of the analysis, poverty estimates and their standard errors are computed. There are two sources of errors involved in the estimation process: errors in the estimated regression coefficients and the disturbance terms, both of which affect poverty estimates and their levels of accuracy. ELL propose a way to properly calculate poverty estimates as well as measure their standard errors while taking into account these sources of bias. A simulated value of expenditure for each census household is calculated with predicted log expenditures  $X_{ch}\beta + Z\gamma$  and random draws from the estimated distributions of the disturbance terms,  $\eta_c$  and  $\varepsilon_{ch}$ . These simulations are repeated 100 times. For any given location (such as a district or a village), the mean across the 100 simulations of a poverty statistic provides a point estimate of the statistic, and the standard deviation provides an estimate of the standard error.

#### 4. RESULTS

We have divided the data into three NSS state regions and within that the focus of the paper is limited to rural area (Appendix 1, Table 2). This division was done because the Orissa state has a population of 36 million. And processing this kind of huge data was very difficult. So we divided the dataset into three parts as per the NSS state region defined in the 61st round. We have used PovMap2 and SAS software for the processing.

Firstly, we need to have a model that should be able to forecast consumption as well as possible (refer to appendix 2). The parameter estimates suffer from omitted variable bias. The parameter estimate is capturing not only the correlation between consumption and the specific regressor in question, but is also reflecting the influence of variables that we have not been able to include in the specification (i.e. omitted variables). The better we are able to capture the influence of these omitted variables, the better the fit we will get from our model (PovMap2 manual guidelines). The key indicator while selecting variables for inclusion in the household regression model is their contribution to the overall R-square of the regression model. However we have also tried to have parsimony of variables in the model. A useful rule of thumb to avoid over fitting was to include no more than the square root of n regressors in the model.

##### 4.1 Statistical Indicators

R-square and adjusted- R-square are used in the context of statistical models whose main purpose is to predict the actual consumption expenditure of each census household on the

basis of consumption model. The R-square is a statistic that indicates how well the predicted expenditure from a consumption model fits the actual household expenditure. The higher R-square means the predicted consumption expenditure fits the actual household consumption better. However, we are using adjusted- R square statistics which show the goodness of fit of the model and also because it is a modification over R-square. An adjusted- R-square increases or decreases depending on whether the addition of another variable adds or does not add to the explanatory power of the model.

The table 2 shows that the adjusted R-square for all the consumption models is more than 0.40. The consumption model shows that in rural areas the location variables were significant and explained the heterogeneity more as compared to urban models. The location variables also indicates that the difference in the governance in term of public service delivery. There significant variance makes the location variables more significant than the household variables. The ratio of variance of eta to the mean squared error (MSE) means how much of total variation can be interpreted by the cluster effect.<sup>8</sup> For all the regions, the variance of cluster at the state region level has been less than equal to 0.5.

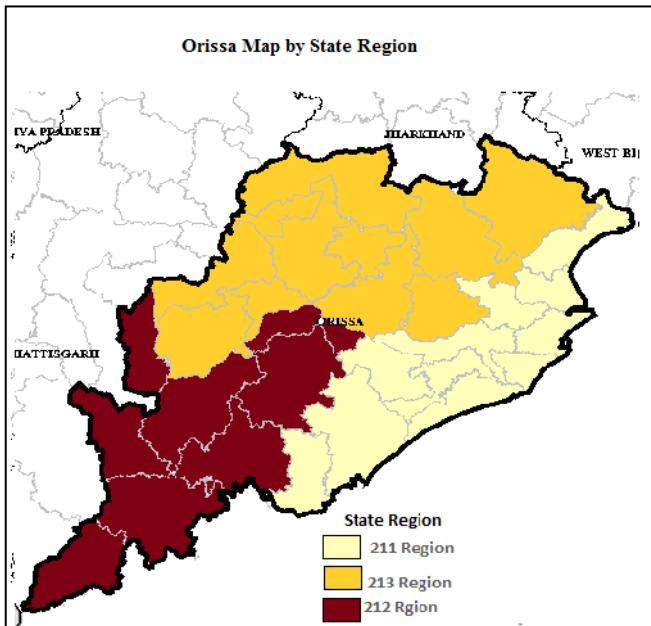

#### 4.2 Poverty Maps

As per the Planning Commission (2004-05) the rural Orissa has 46.8 percentage of the population below poverty line. The rural Orissa is significantly poorer than the national average (i.e. 28.3 for rural-all India). We have divided that state of Orissa into three state region (mentioned earlier). The colour shading indicates the degree of poverty in the state region. The darker colour means more poverty than the lighter color (uniform colour coding used in all maps). Within the state, state regions are divided on the basis of similar agro-climatic conditions. The state region 211 (refer figure 2) consist of coastal districts which are actually better than the state average but not so much better off than the national average BPL proportions. The state region 212 is poorer than state region 213 and state region 211. The state region 212 happens to have dense forest.

---

<sup>8</sup> The word ‘cluster’ is an aggregation level in the survey and census datasets.

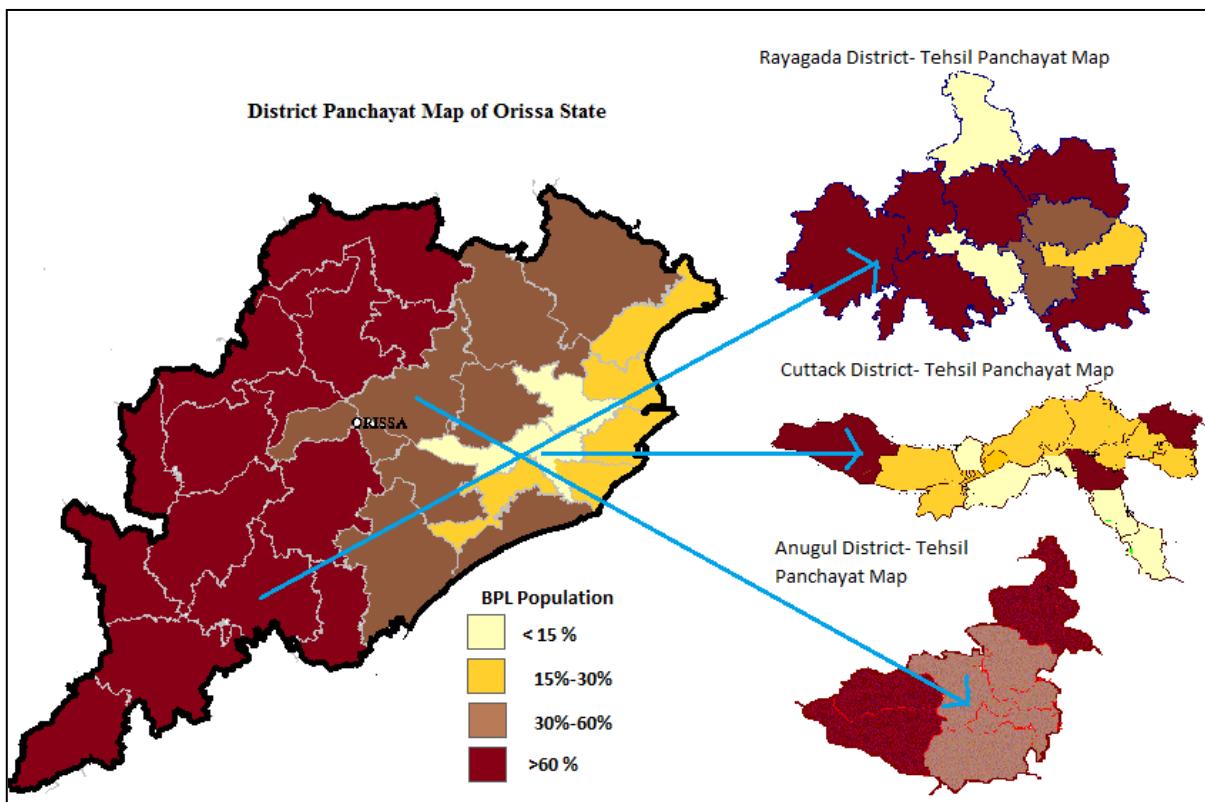

**Figure 2: State Region-wise Map of Orissa**

Poverty maps of the 30 district Panchayat in Orissa are shown in Figure 3. The district Panchayat shows huge variation in the level of poverty within the state. However to look at the disaggregate level we picked three districts namely Rayagada, Anugul and Cuttack. The Rayagada district panchayat which has more than 60 percent BPL population shows that not all the tehsil panchayats are extremely poor. There are pockets of tehsil Panchayat which are having less than 15 percent BPL population within an extremely poor district Panchayat.

In contrast, the Cuttack district panchayat have less than 15 percent BPL population. But we can find some of tehsil Panchayat are extremely poor (more than 60 percent). When we look at the Anugul district Panchayat that is closer to the state's average BPL population, we find that poverty is more or less uniformly spread across tehsil Panchayats. Thus, targeting at the district Panchayat can significantly miss the poorer areas within the state or district Panchayat level. We have not included gram Panchayat maps as they were not available. The poverty estimates at the district, tehsil and gram Panchayats are given in (Appendix 3).

**Figure 3: Power of Disaggregation of Poverty Estimates-- Rural Orissa in India**

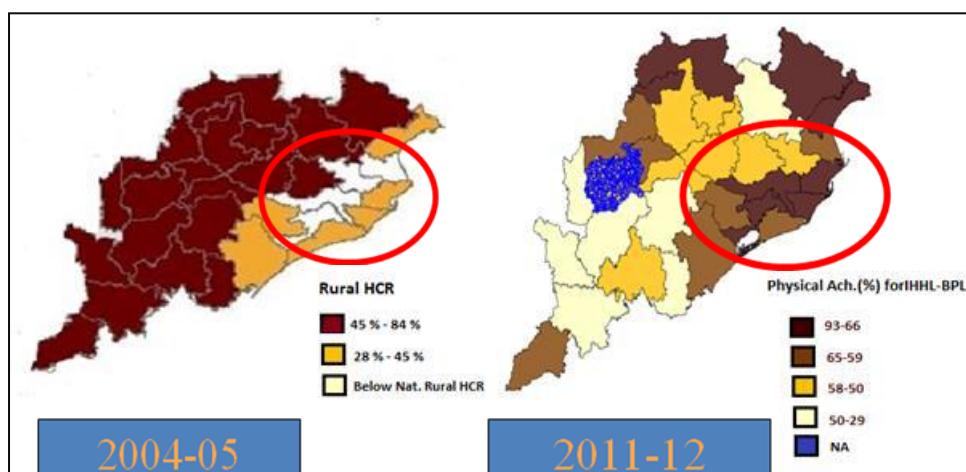

#### 4.3 Example Illustration: Poverty Map and Welfare program

The Census 2001 figures showed that rural sanitation coverage in India was only 22 percent. And immediate concrete efforts were needed to improve the standard of living among the rural households. The government of India started the Total Sanitation Campaign (TSP) which is a comprehensive programme to ensure sanitation facilities in rural areas with the broader goal to eradicate the practice of open defecation by 2017.

Now it is important to know more about where TSP works best and where it is unlikely to work well because of the differences in the socio-cultural, physical and political environment. We have selected 'Individual Household Latrine' (IHHL) for below poverty line population

as our basic criterion to analysis TSP for our study. We find that correlation between poverty estimates and percentage of physical achievement (by the TSP program) in 2001-02 was (-0.66) and in 2011-12 (+ 0.30). Under the component IHHL, provision exists for providing incentives to BPL households on completion and use of toilets in recognition of their achievement. However, the poverty map of 2004-05 and 2011-12 shows that the area with the high poverty has lowest physical achievement as per the TSP program. The map (Figure 4) on the left show the poverty estimates in the year 2004-05. The darker colour means more poverty as compared to the lighter colour. On the other hand, the map on the right hand side shows the physical achievement of IHHL-BPL. The darker colour means higher physical achievement as compared to lighter colour. This means that areas with the high poverty, the physical achievement was very low for IHHL -BPL population (highlighted in the red circles). These kinds of allocation mismatch help us answer the question like how much the problem is institutional, how much is due to data gap and how much of the problem is due to bad design of the interventions.

**Figure 4. Misallocation of the resources**

Note: The map of on left shows the Poverty estimates for the year 2004-05 and map on the right hand side shows the physical achievement for IHHL-BPL (2011-12).

## 5. CONCLUSION AND LIMITATIONS

The policies are made looking at the macro estimates. But today more and more policy makers are demanding estimates at the micro level for its use in the policy decisions. The local self government such as district Panchayats, tehsil Panchayats and gram Panchayats are taking on a greater role in the long term planning and socio-economic development of their areas. This increases the need for small area estimates to measure welfare indicators at the lower level of disaggregation. The convergence of information for the various welfare

indicators at the disaggregate level i.e. tehsil can be helpful in planning, better targeting and delivering services to the people. Secondly, the disaggregate information will help in efficient resource allocation. Finally, in the decentralisation set-up of governance, identifying poverty pockets and prioritisation would be useful. Overall, this can be a useful tool to target, design and monitor programmes at disaggregated levels.

On the other hand, the limitation of the small areas estimation technique is how do we know that the results are valid. And what should be our level of disaggregation. To know whether the results are valid, we can do three things. Firstly, we can conduct a small census of Panchayats within the state to validate our results. The Panchayats can be randomly chosen for this exercise. Secondly, we can superimpose other disaggregated source of information like satellite images, remote sensing data, roads, weather etc. upon our poverty maps to establish the correlation. Like, Henderson (2010) suggests the brightness of visible lights is strongly related to both population density and income per capita. Thirdly, we can conduct interviews with the elected Panchayat representatives to validate our results. Beside this the Elbers et al. (2004), suggest that a useful way forward might be to combine fine geographic targeting using a poverty map with within-community targeting mechanisms.

However, we have not tested for optimal level disaggregation in this paper. The results of this paper should be used for designing, pilot testing of welfare program and planning and monitoring of welfare programs.
