Abstract

The present study aims at analysing different stratification criteria used in Brazil by market research companies and academia, taking into account family profiles based on demographic, socioeconomic and expenditure variables. It presents different strata profiles generated by two nationally well-known stratification criteria based on survey data from two last editions of the Brazilian Family Expenditure Survey (2002/2003 and 2008/2009) and provides evidence on patterns of change over time. The motivation for the work is the great attention Brazil is attracting nowadays as the country has experienced reduction on poverty over the last 10 years and academic studies reached news headlines indicating that a substantive portion of the population has managed to move out of poverty to constitute an emerging group that is nationally known as the *new Brazilian middle class*. The paper provides evidence of this new phenomenon and the results confirm an economic improvement over time for those individuals classified in the lower socioeconomic stratum, together with an increase of total and per capita average income, and an increase of expenses. On the other hand, there is also a visible reduction of savings for families in all economic strata and higher levels of household indebtedness are observed.

Keywords: Socioeconomic stratification, household expenditure, household income, family consumption, savings.

1. Introduction

Over the last two decades, better levels of family income and wellbeing have been registered in the Brazilian economy as the result of well succeeded plan to stabilize prices, coupled with a set of government actions related to income transfer programs, credit access to low income population, real gains in the minimum wage, overdraft facilities, among other measures (Lacerda,2009). Over the last 10 years, poverty has been reduced indicating that a substantive portion of the population has managed to move out of poverty to constitute an emerging group that has been identified by many as the *new Brazilian middle class* (Neri, 2010). The rise of the so-called new middle class has given support to a boom in the domestic consumer market, and has contributed to sustain economic growth in the last decades. Indeed, the new middle class would be composed by younger people, with higher educational level and so with higher consumption standards.

The emergence of the new Brazilian middle class is, in fact, an issue of debate among academics. Even considering that the consumption per capita has been increasing over the years²,

¹ Real minimum wage increased over 70%, almost 4 times more than in the previous decade (18%), between 2002 and 2012.

² Based on National Accounts, family consumption has grown 3.3% per year and the GDP 3.1% per year, from 1995 to 2011. Considering the recent period, 2004 to 2011, these rates were, 5.4% and 4.2%, respectively.

many authors reject the idea that there is a new middle class in the country. Pochmann (2012), for example, focusing his work on income evolution, states that the increase of the consumption pattern does not indicate social mobility. According to him, the increase of per capita consumption points in fact to a market phenomenon instead of a real transformation of socioeconomic nature as well as its dynamics of the Brazilian society. Scalon and Salata (2012), based on a sociological approach, argue that movements in the class structure might not have been significant enough to support the idea of a rising new social class, or even that the traditional middle class has expanded.

In other to shed some light on this debate, this paper is concerned with a methodological issue focusing on the stratification criteria of socioeconomic classes. As the improvement in the income distribution is a new phenomenon in the Brazilian society, the reason for this concern is that it has become popular the dissemination of figures highlighting the rising of the living standards of Brazilian families. However, there is not a unique way of defining socioeconomic classes, and in most cases, no reference about which stratification criteria has been used is made.

Actually, few studies concerned with the evolution of living standards compare different economic stratification criteria in order to explain how consumption habits have evolved, and also very important, how it has been financed. Therefore, this paper intends to contribute for the understanding of the changes in class stratification profile in Brazil. To enlighten the discussion about the rising of a new middle class, it provides empirical evidence about socioeconomic characteristics and consumption habits of groups of people and on how they managed to finance their consumption expenses. Our results confirm an economic improvement over time for individuals classified in the lower socioeconomic stratum, together with an increase of total and per capita average income, and an increase of expenses. On the other hand, there is also a clear reduction of savings for families in all economic strata and so higher levels of household indebtedness are also observed.

The empirical study reproduces two stratification criteria used in Brazil: one by market research companies and the other by academics. We replicate both criteria using survey data from the two last editions of the Brazilian Family Expenditure Survey (2002/2003 and 2008/2009). The criterion called *Brazil Criterion* was developed by market research experts and, like many other social grade criteria around the world, is used as a good discriminating function for purchasing power. The other, developed by academics, is mainly based on per capita income and has been used to discuss issues related to poverty alleviation. This will be named here as the *Center for Social Policies* stratification criterion, with a reference to the research institution located in Rio de Janeiro (Centro de Políticas Sociais – FGV) where the criterion was created. The paper identifies strata membership according the two different criteria based on survey data and examines the strata profiles taking into account expenditure, income and debt related variables.

As a result of our empirical work, we reveal differences between household profile variables related to the two types of stratification criteria, which we believe are relevant to different research fields that make use of socioeconomic stratification to identify differences in living standards. These research areas are mainly in administration and communication, where one studies consumer patterns, and in economics with emphasis on public policy analysis. In relation to marketing studies, advertising agencies and firms in general must have a clear understanding that each of the criteria is built considering different definitions of income: the Criterion Brazil uses household total income, and the Center of Social Policies approach takes into account per capita income. The first approach prioritizes consumption decisions, while the

latter is closely linked to the notion of welfare. Researchers in public policy, on their turn, should consider that, as in either criterion household expenditure depends on the level of budget constraint, it is important that the government examines critically the evolution of income and savings, in order to be able to guide families on how to manage their budgets. Initiatives related to capacity building on personal and family financial management are a valuable instrument to make people aware of the essential need of planning financial spending.

This paper is organized as follows. Section 2 briefly describes both stratification criteria that will be analyzed, and Section 3 presents the main characteristics of the Brazilian Family Budgetary Survey, which will be the reference of our empirical analysis. The methodology employed in this paper is described in Section 4 and Section 5 presents our results, describing our findings according to economic and demographic variables. Finally, Section 6 presents the main conclusion of our study.

2. Socioeconomic Stratification Criteria as Discriminatory Tools

França (2010) pointed out that there is no consensus in relation to the choice of a specific stratification technique or social grade criterion. This choice must be made based on research objectives. One criterion can be more appealing if the specialist is interested on its use as a discriminatory tool to investigate purchasing power characteristics of a group, family or individual whereas the other may be considered as a measure related to income distribution and can be more adequate to reflect changes in wellbeing regarding poverty alleviation. Therefore, studies focussing on social inequality or socioeconomic and market segmentation, for example, serve different purposes, and require different measures to be taken into account as a barometer of change. Both criteria discussed in this paper are described below.

The Brazil Criterion

According to the Brazilian Association of Survey Companies - ABEP³ (2007), the "**Brazil Criterion**" of economic classification main goal is to estimate the purchasing power of individuals and urban families. This stratification criterion aims at generating a standardized scoring system that could work as a predictor of individuals' and families' consumption capacity, able to discriminate large groups according to their capacity for consuming products and services that are accessible to a significant part of the population. The criterion discrimination procedure takes into account tangible household characteristics such as possession and quantity of durable goods, number of bathrooms, employment of domestic workers and educational level of the head of household. Each item receives a score and the sum of scores is then associated to an economic grade or stratum - A1, A2, B1, B2, C1, C2, D and E – (details in França, 2010).

However, despite being largely employed, this criterion is questioned due to some limitations. Mattar (1994, 1996) argues that there is not a consensus on which variables should be taken into account to define a classification criterion that could effectively group consumers in a way that the groups could match the several stereotypes recognised in the market environment. In addition, the effect of family size (as the score is based on quantity and possession of goods in the household), and the massification of durable goods over time are viewed as weaknesses of the Brazil Criterion.

³ Brazilian Association of (Market) Research Companies - http://www.abep.org/novo/Default.aspx

The criterion defined by the Center for Social Policies (CPS)

This criterion has a similar approach to the one generally used for the analysis of poverty issues related to the so-called absolute poverty concept and it is based on household per capita income. The lower economic stratum (named E) is comprise of families with household per capita income below (or equal to) a poverty line⁴. The subsequent stratum (D) belongs to families whose household per capita income is situated between the poverty line and the median of the distribution. Next, the families in class C are those with household per capita income between the median and the ninth decile of the income distribution and, finally, the so-called AB class is composed of families with household per capita income above the ninth decile (Neri and Melo, 2008).

3. The Brazilian Family Expenditure Survey

The Brazilian Family Expenditure Survey, conducted by the Brazilian Institute of Geography and Statistics, has a probabilistic sample and the survey target population comprises those living in urban and rural areas. The survey aims at uncovering families' consumption structures that allows delineating the population life conditions based on their household budget and corresponding expenditure. The survey has several units of analysis: consumer units, households, families, individuals, and the products (listed on the expenditure questionnaire). The data collection period lasts 12 months, in which it is possible to capture changes on family budget across the whole year, embracing all income and expenses variations that may occur on the annual budget (IBGE,2010)⁵. For this paper, various calculations have been done for consumer units, since most of the household expenditure data is collected at this level, and the terms consumer unit, family, and household may be used interchangeably for convenience.

4. Methodology

The methodology consists on identifying strata membership of consumer units according the two different criteria based on survey data from the 2002/2003 and 2008/2009 editions. In the case of the Brazil Criterion, the calculations were done based on the classification scoring card defined in 2007. The analysis compares results of two distinct criteria of socioeconomic classification for two different periods in order to point out different perspectives of strata profiles considering economic variables, such as income, type of income, debt profile, expenditure, as well as demographic variables such as composition of the consumer unit, types of family arrangements and level of education. As the Family Expenditure Survey has a complex sample design, the estimation procedure took into account the sample weights.

Income and expenses estimates of 2002/2003 were adjusted for inflation in order to be compared with the 2008/209 estimates. In addition, a debt indicator was created. A consumer unit is considered in debt if its annual expenditure exceeds the annual income. If the indicator calculated as the ratio of total expenditure in relation to total income gets a value below 1, this indicates that the consumer unit has not committed the entire annual family budget with consumption.

⁴ For this study, poverty line has the value of 135 reais (66 US\$). Exchange rate on Jan 18th, 2013.

⁵ http://www.ibge.gov.br/home/estatistica/populacao/condicaodevida/pof/2008_2009/POFpublicacao.pdf

As this paper is based on a quantitative study, it is not possible to capture, in a qualitative way, the similarities and differences related to expenses type within each group of expenses. Also, the main descriptive statistics employed to summarize the variables is the mean, a central tendency measure that is influenced by extreme observations. Another limitation here is due to the fact that it was not possible to carry out a longitudinal analysis, in a panel style, since the families cannot be identified or monitored through survey editions. We produce a photograph of the strata configuration in each survey edition and compare them. At last, it is worth mentioning that this study only captures the changes related to expenses and incomes in two fixed occasions but not the stock of these quantities.

5. Results

5.1 - Percent distribution of strata

Table 1 presents the percent distribution of consumer units by strata. Both criteria show poverty alleviation and increase of family consumption in the lower strata over time. Although this study is not based on panel data, it can be suggested that families that were positioned in stratum E have ascended to stratum D, and some of these to stratum C. The reduction of the lower strata can be associated with government income transfer programs⁶ driven to families in a situation of extreme social vulnerability.

Table 1: Percent	distribution of	of consumer	units by	stratification cr	iteria
	GIDGITO GCIOII	or companier	carried o	buduiteduion or	Ittia

	Brazil Criter	ion	Center for Social Policies							
Strata	2002/2003	2008/2009	Strata	2002/2003	2008/2009					
Α	1.61%	1.18%	AB	10.00%	10.00%					
В	12.07%	14.71%	С	40.00%	40.00%					
С	32.38%	42.73%	D	32.56%	42.92%					
D	40.34%	34.35%	E	17.45%	7.08%					
E	13.59%	7.03%								

Indeed, the changes in the composition of the stratum in both criteria between the two periods are also very revealing of the movements that might have occurred among the strata. In the 2002/2003 period, stratum D was the one with highest weight according to the Brazil Criterion. Looking at the 2008/2009 period, stratum C, commonly associated to the so-called middle class, appears as it is congregating more consumption units, suggesting the upward movement among consumer units. On the other hand, in the case of the Center for Social Policies criterion, the mobility among the strata seems to have been higher from stratum E to stratum D, as the percentage of middle class strata has not changed between the two periods.

Table 2 allows the comparison between the two criteria since is displays the percentage of consumer units in each stratum of Center for Social Policies that was classified in a similar way based on the Brazil Criterion. In the 2002/2003 period, 63% of the families classified as belonging to the stratum AB by the Center for Social Policies criterion were also classified as belonging to the stratum A or B of Brazil Criterion. The same occurs in 2008/2009 when this percentage was 62%. This substantial overlap of both criteria does not hold for stratum D and E.

⁶ http://blogs.worldbank.org/growth/brazil-fights-hunger-illiteracy

An explanation to this divergence is the greater capacity of families with lower income to purchase goods, following better opportunities to credit after mid 2000s. If this is the case, the Brazil Criterion better captures this movement, as it takes into account the quantity of goods in the household, whereas the Center for Social Policies criterion considers the per capita income evolution.

Table 2 - Percentage of consumer units per strata classified according to both criteria in 2002/2003 and 2008/2009.

	Е	0%	8%	49%	42%	100%		Е	1%	14%	53%	33%	100%	

5.2 - **Income**

A comparison between 2002/2003 and 2008/2009 estimates of average monthly real income and average per capita real income in Table 3 shows improvements in most of the strata.

Table 3 – Average Monthly Real Income and Average per Capita Monthly Real Income per Consumer Units in US Dollars by Strata According to Two Stratification Criteria

		Brazil Criter	ion		Center for Social Policies							
	Average	Monthly	Average	Per capita		Average	Monthly	Average Per capit				
Strata	Inco	ome	Monthly Income		Strata	Inco	ome	Month	lly Income			
	2002/03	2008/09	2002/03	2008/09		2002/03	2008/09	2002/03	2008/09			
Α	6999	8655	1995	2627	AB	4632	5156	1929	2338			
В	3207	3319	1130 1259		С	1219	1434	395	517			
С	1198	1235	435	475	D	495	590	132	166			
D	551	619	193	248	Е	232	215	48	45			
E	310	381	110	151								

In the case of the lower stratum defined by the Center for Social Policies, the socioeconomic ascension of some families to the D stratum from 2002/2003 to 2008/2009 yields a shrinkage effect on the estimates. There is now evidence that this E stratum congregates only those families with very low income. Although this stratum is comprised of fewer families in 2008/2009, these are the families who were still in an extreme vulnerable social condition. Overall, the combination of more access to credit, higher real income levels and controlled inflation provided the adequate conditions to promote gains in the families' purchasing power.

5.3 - Expenditures categories and corresponding contribution to family budget

Considering both criteria, there is great similarity in the way families spend their income according to different expenditure items and different strata. As expected, the housing category is the one with higher impact on family budget followed by vehicles and additional expenditures for families in middle or higher strata. On the other hand, as it is usually the case, a substantial

part of the budget is used for food expenses in case of families in the lower socioeconomic strata. It is important to highlight that, associated with an increase on income, it can also be noted a rearrangement on the composition of expenditures, particularly for the strata defined by the Center of Social Policies. For families in stratum D, from 2002/2003 to 2008/2009, there is evidence that, in relative terms, the contribution of expenditures with food, clothing and footwear, vehicles plus personal goods and services have increased. Consequently, expenses with housing and repair represent nowadays a lower percentage indicating a change in purchasing habits of this group of people, the so called 'new' Brazilian middle class.

5.4 - Types of income

This section discriminates different sources of income in order to contribute to a better understanding of changes in the consumption pattern according to stratification criteria. A brief analysis of Table 5 indicates that the only type of income with decreasing participation is the financial asset movement, which is the difference between deposits and withdrawals in each stratum. Among the types of income showing increase in the proportional weight, the one that stands out with higher participation is the income obtained from main occupation, public pension and income tax deductions. Comparing the results across time, one can notice a striking drop of participation of financial asset movement group in relation to the total income. Contrasting 2002/2003 with 2008/2009, there is evidence of a sharp drop in savings. The consumer units reduced their savings in this period in order to finance their augmented spending. A clear example of this behaviour is what happened with the consumer units in stratum D of Brazil Criterion that achieved a debit balance on this group of income in 2008/2009. In general, it is possible to sign that family consumption among strata has been markedly funded by a reduction in savings, and also by the contraction of loans, since that have been an increase in the average value contracted for modality.

5.5 - Debt situation

Data about debt situation reveals that improvement in consumption pattern in all social strata was followed by an increase in the degree of indebtedness of households. This means to say that, although income for all different strata has improved in the 2000s, there has also been an increase on the proportion of consumption units in debt situation in all strata levels, except stratum E.

It is relevant to point out that more than half of the consumption units in the population were in debt situation in 2008/09. The worst case is observed for stratum E that, even showing reduction of the percentage of families in debt from 2002/03 to 2008/09, is nonetheless the most affected group in both criteria (Table 6).

There are many reasons why debt commitment has increased so widely among consumer units in the 2000s: favourable expectations about the future, price stability, increase in employment rate, decrease in interest rates, and so on. Also, bank institutions changed their strategies, as the degree of confidence in the future prospects of the Brazilian economy was improving. Therefore, one should consider that banks, under greater competition due to economic opening and in an environment of stable inflation, identified potential gains in loans to households, supported by optimistic expectations regarding the recovery of employment and income under the Lula government (Prates et al, 2009, p. 5). On the other hand, regulation concerning access to credit changed in 2003, when a special type of personal credit, the consigned loans (or payroll loans as banks are allowed to discount the pay back of loans direct from wages deposits) has been authorized. ⁷ Actually, a change in Central Bank regulation expanded this type of credit to all employees and retirees, as before 2003 it was restricted to civil servants. According to Central Bank (2005), this sort of loan stimulates competition among bank institutions and smaller as well as bigger banks took advantage of this opportunity of expanding credit. Indeed, Central Bank time series shows that in 1995 consumer credit was 8% of total credit and in 2008 it reached to 33%.

Therefore, the government strategy to give access to credit to all social economic classes must be seen as noteworthy to boost aggregate consumption expenditure and to contribute to social mobility.⁸ However, the high level of indebtedness also imposes limits to family expenditure plans. Hence, as the access to credit came in very forcefully, households are now facing new constraints as families budgets are committed to pay debts (Sciré, 2009).

Table 6 – Percentage of Consumer Units in Debt Situation

-

⁷Law 10.820, December 17, 2003.

⁸ As pointed out by many authors, the large size of the Brazilian domestic market was a positive factor to help the country to overcome the negative impacts of the external crisis in 2009/2010. This model, that it is to say, to increase aggregate consumption increasing debt commitments seem to have reached to its limit, as Brazilian GDP did not recover in 2011, neither in 2012 or in the first semester of 2013.

5.6 - Average number of persons per consumer unit

Comparing the number of persons per consumer unit, which is a key characteristic related to consumption pattern of the households, we observe that the average number of persons per consumer unit is similar among strata in the case of Brazil Criterion (Table 7). Considering the Center for Social Politics criterion, the number increases from stratum AB to stratum E, pointing that richer families have on average few people per household.

Table 7 - Average number of persons per consumption units by strata in 2002/2003 and 2008/2009

	Brazil Criterio	on	Cente	r for Social I	Policies		
Strata	2002/2003	2008/2009	Strata	2002/2003	2008/2009		
А	3.97	3.69	AB	2.58	2.38		
В	3.51	3.31	С	3.13	2.81		
С	3.51	3.26	D	3.81	3.70		
D	3.63	3.28	E	5.03	4.89		
Е	3.97	3.50					

The difference between the average number of persons per stratum in each criterion can be explained by its corresponding method of construction. The Brazil Criterion method is based on the quantity of durable goods in the household and hence the consumption units with more people own more domestic items. This may explain the higher number of persons per household in the stratum A.

For the other criterion, the classification is based on per capita household income, the same information used to establish poverty line and the strata limits are defined according to the deciles of the empirical income distribution. In this way, a household with low per capita income can associated to more residents with less income.

5.7 - Types of family arrangements

Types of family arrangements vary considerably among criteria. Table 8 provides evidence that the choice of a stratification criterion implies that the analyst would deal with different profiles of family arrangements.

In the case of Brazil Criterion, for example, couples with children older than 15 years represent almost 40% of the families classified in stratum A whereas couples with children younger than 15 years have higher percentage in strata B, C, D and E. One should also note that those families with only one person correspond to the type of arrangement that has the second higher participation in stratum E. On the other hand, for the Center criteria, families with only one person and couples without children have higher participation in strata AB and couples with children younger than 15 years are over-represented in strata D and E. The one person family is classified in different strata in each of the two criteria. One reason is that the Brazil Criterion takes into account the possession of durable goods and the employment of housekeepers, which are converted to points in a scale. However, individuals who live alone may not necessary own (or even need) a quantity of durable goods to be positioned in the higher strata (they may eat out more frequently and make use of laundry services, for example).

Conversely, individuals who live alone only do so when they have financial conditions to pay for housing and other maintenance costs. The fact that the per capita income is the variable used to define the strata boundaries in the case of the Center for Social Policies criterion, gives rise to an inverse situation. It places individuals who live alone in the higher stratum, generating noteworthy participation of this arrangement in stratum AB. The contribution of this type of arrangement has a decreasing trend from stratum AB to E. The lower stratum is mostly composed of families with a higher number of children and couples with children younger than 15 years. The latter group may also include couples with young children at beginning of their professional careers.

5.8 - Head of household educational level

The Brazil Criterion method takes into account the head of household educational level such that those households with more educated heads are better classified according to this criterion. This is due to the well-known positive correlation between level of education and income, so that consumption units whose heads have high level of education have more chances to belong to stratum A. Table 9shows that, in 2002/03, 86% of consumer units classified in stratum A have head of household who had attained a university degree, whereas this percentage falls to 63% in 2008/2009.

As for the Center of Social Policies method, the level of education of the head of the household is not a specific constraint for the stratification procedure (although here also there is effect of correlation between education and income), the percentage of consumer units whose head of household holds a university degree is much lower in stratum AB than in the Brazil Criterion.

Table 9 - Percent distribution of highest level of education attained by head of household by strata

Brazil Criterion - 2002/2003 and 2008/2009

Level of Education	Α		В		(0	[)	Е		
Level of Education	2002/2003	2008/2009	2002/2003	2008/2009	2002/2003	2008/2009	2002/2003	2008/2009	2002/2003	2008/2009

University degree	86.05%	62.56%	35.87%	20.10%	3.17%	2.08%	0.03%	0.08%	0%	0%	

Center for Social Policies - 2002/2003 and 2008/2009

Level of Education	AB		(С)	E		
Level of Education	2002/2003	2008/2009	2002/2003	2008/2009	2002/2003	2008/2009	2002/2003	2008/2009	
Basic - up to 4th grade	10.38%	10.17%	22.89%	29.17%	41.99%	41.72%	56.83%	55.20%	
5th to 7th grade	12.44%	8.03%	28.68%	20.35%	34.37%	28.33%	30.38%	27.83%	
Middle - 8th grade	8.16%	3.89%	15.78%	10.61%	13.59%	12.56%	8.34%	9.97%	
Secondary - up to 12th grade	32.69%	53.90%	25.48%	35.15%	9.39%	16.69%	4.23%	6.63%	
University degree	36.33%	24.01%	7.17%	4.71%	0.67%	0.70%	0.23%	0.37%	

Finally, it is understood that choosing one or other stratification criterion generates different profiles of consumer units according to the educational level of head of household and consequently different patterns of consumption.

6. Conclusion

Brazilian GDP growth in the first decade of the 2000s was driven by consumption of the families, since low inflation, well-focused social programs and a policy of real increases for the minimum wage has improved income distribution, expanding domestic market for consumer goods. The increase in consumer credit has also played an important role in sustaining higher levels of per capita consumption and changing consumption patterns. All these movements have impact in the socioeconomic stratification, and an important debate emerged among academics and in the media about the rise of a new middle class in Brazil. To contribute to this debate, this paper evaluated two different class stratification methodologies, which reveal slightly different characteristics about the changes in consumption pattern according to socioeconomic stratum. Economic and demographic variables were investigated in order to differentiate both criteria.

Both methodologies reveal a decrease at the participation of lower strata, increase of participation of medium strata, increase of total and per capita income, increase on average expenses and increase on average income. The Brazil Criterion exposes a raise on the consumption potential and the Center for Social Policies criterion signals a poverty alleviation condition. So, both criteria show an improvement in social mobility with positive impact on aggregate consumption in the period. However, the Brazil Criterion methodology puts more weight on demographic characteristics than the Center for Social Policies methodology, and in this sense, it tends to give less importance to the degree of indebtedness as a problem to inhibit future consumption.

Therefore, our exercise also evaluated the degree of indebtedness according to the economic strata in both criteria and we concluded that this degree has increased for all strata, except for the

lower stratum which was the one with the highest commitment to debt loans in the 2002/03 period. This is an important contribution of our work, since the sustainability of the private consumption as a driving force to push economic growth can be constrained by the financial fragility of family's budget. Indeed, the low response of the Brazilian GDP growth in the last years (2011, 2012 and current 2013) has been attributed to an exhaustion of the growth model driven by domestic consumption.

In general we could show that in both criteria there is a trend in the direction of families consuming more, using their savings and reducing their wealth. In aggregate terms, this implies a transfer of income from families to the financial sector. In this sense if, on one hand, almost universal access to credit has reframed the possibility of consumption in the second half of the first decade of the 2000s, dissociating it from income earnings and savings, on the other hand has brought another concern to indebted families. This means to say that these families, which are spread in all socioeconomic strata, have to manage the payment of debt commitments in an environment of increased uncertainty in relation to the future.

Besides economic variables, this paper also investigates some demographic characteristics of the households in both criteria: average number of persons per consumer unit; types of family arrangements and level of education of the head of household. Demographic characteristics suggest how families make their consumption choices, while economic variables signal the possibilities, that is to say the budget constraints families have to deal with concerning consumption expenditures. Although demographic characteristics tend to change little over a short period of time, we could observe that the distribution of consumer units by level of education of the head of household has changed from 2002/03 and 2008/09 for the highest stratum in both criteria. This change occurred in the direction of reducing the weight of the university degree group. This is an interesting finding as it shows a reduction in the importance of graduate schooling as determinant to be included in the higher social economic class. Also it reveals the relevance of having the secondary schooling degree concluded in order to be better positioned in socioeconomic stratification.
